

Introduction

Enterprise telecom connectors-based development is commonly fragmented across specification reading, JAR artifact inspection, response mapping and YAML authoring, and script-based generation. Digital Horizon Connectors unifies this lifecycle into one guided workflow to improve consistency, traceability, and visibility.

Problem Statement

Enterprise connector modules must follow legacy Maven structures and deployment constraints. Manual steps mapping and configuration often cause & introduce inconsistencies, structural errors, and weak traceability across the connector lifecycle.

Solution

Digital Horizon Connectors unifies enterprises connector development into five phases : Module set up , API specification ingestion , JAR metadata mapping , user-config generation and module generation. This approach improves consistency , traceability and end-to-end workflow and less manual intervention.

Techniques Utilized

- **MERN-Stack:** provide a unified connector flow.
- **Shell-Scripting:** provide automation to the whole application.
- **Maven:** Used to package, build and maintain the application.
- **Java:** Whole automation tool backend is used in Java.
- **Tomcat:** It is used to deploy the application.

Conclusion

Digital Horizon Connectors demonstrates that a unified, workflow-driven platform can effectively replace fragmented manual connector development by improving consistency, traceability, and end-to-end operational visibility while remaining compatible with enterprise Maven-based integration constraints.

Future Work

Future enhancements include JWT+RBAC security, cross-platform generation, native DB-backed storage, automated testing, frontend modular refactoring, and containerized deployment with Docker/Kubernetes.
